REVIEW DRAFT

BROADACRE / SOIL TESTING

Soil testing checklist

A soil report should help you decide what to do in the paddock. Start with the results you already have, then work out whether new sampling is needed and how the findings will inform a practical Nutrient plan.

01 Be clear about the paddock question

- ☐ Identify the paddock, intended crop, area and the decision you are trying to make. Note uneven growth, different soil types or other constraints you want to investigate.
- ☐ Gather existing soil reports, yield records and recent Nutrient applications. Keep sample dates, locations, depths, methods and units with the results.
- ☐ Tell your agronomist what you want to achieve and the budget and equipment you are working with.

02 Get a sample that represents the area

- ☐ Agree which areas should be sampled separately. Combining very different areas can hide information that matters to a recommendation.
- ☐ Confirm the sampling depth, number of cores, collection method and handling with your agronomist and laboratory. Use their current instructions.
- ☐ Record where and how the sample was collected. Note recent applications or unusual conditions that could affect interpretation.

03 Read more than the headline numbers

- ☐ Ask what the selected analysis includes. Discuss Nutrient results alongside pH, salinity and other relevant soil properties, rather than treating one number as the whole answer.
- ☐ Check that methods and units are comparable before drawing a trend from different reports.
- ☐ Combine the report with paddock observations, crop demand and relevant field history. A soil test does not explain every physical or biological constraint.

A plan for your paddock

04 From a report to kilograms per hectare

- ☐ Ask your agronomist to explain the interpreted Nutrient requirement in kg/ha, including the assumptions, soil contribution and crop demand behind it.
- ☐ Where a requirement is established, develop a Hybrid-Ag prescription blend and application plan suited to the paddock and budget. Check what each proposed rate supplies.
- ☐ Agree what needs action now, what can wait and how you will check the response. If the evidence is incomplete, resolve that before settling on a rate.

> A laboratory concentration is not an application rate. Expressing a result in kg/ha needs an appropriate soil-depth and soil-mass basis, with bulk density and gravel considered where relevant. An extracted amount is not automatically all available to the crop.

Paddock / crop / hectares

Question we need to answer

Existing reports / sample dates

Sample depth / locations / method

Nutrient requirement / assumptions

Agreed action / next review

Got a report you want to make sense of?

Ask for a chat with James White about existing results or arranging comprehensive soil testing. You can also register interest in a soil-testing webinar. Dates and presenters are still to be confirmed.
