REVIEW DRAFT

BROADACRE / SOIL TESTING

Soil testing checklist

The value of a soil test is in the recommendation that follows it. Use these points with your adviser to turn the raw readings into Nutrient requirements, decide what is worth correcting and develop a prescription that suits your soil and budget.

01 Check the analysis covers what you need

- ☐ Check that the analysis covers the relevant major and Trace Elements, alongside pH, salinity and other soil properties needed to interpret the results. Agree any gaps before paying for another test.
- ☐ Review Nutrient results alongside constraints such as compaction or drainage. An application may not resolve the underlying reason an area is underperforming.
- ☐ Compare historical results on a consistent basis. Differences in sampling depth, analytical method or units can change the apparent trend.

02 Target the samples before you collect them

- ☐ Use DataFarming NDVI imagery with yield records and paddock history to identify contrasting production areas. Check the pattern on the ground before choosing sample zones.
- ☐ Sample contrasting zones separately where results could change the prescription. Mark locations with GPS coordinates, for example in Google Earth, to guide repeat sampling.
- ☐ Agree depths and methods with your adviser and laboratory. A field pH indicator can screen for acidity down the profile; confirm suspected layers with separate-depth laboratory samples.

03 Turn the readings into kg/ha requirements

- ☐ Work with an adviser who can interpret the raw readings into Nutrient requirements in kilograms per hectare to improve soil balance. See page 3 for the standard-test comparison and Hybrid-Ag's approach.
- ☐ Have the adviser explain which deficits or excesses warrant action and where a blanket application would supply Nutrients the soil does not need.
- ☐ Check the basis of the kg/ha figures, including sampling depth, soil mass and the laboratory method. Separate the interpreted soil requirement from the eventual fertiliser rate.

A plan for your paddock

04 Build a prescription around the requirement

- ☐ Use the interpreted kg/ha requirements to develop a Hybrid-Ag prescription blend, accounting for existing Nutrient contributions, crop demand, application options and budget.
- ☐ Check what the proposed blend and rate actually supply per hectare. Resolve any unnecessary additions or remaining gaps before settling the recommendation.
- ☐ Prioritise the corrections if the full recommendation exceeds the budget. Agree what to address first and what follow-up testing would justify the next investment.

> Converting a concentration into kg/ha requires an appropriate soil-depth and soil-mass basis, with bulk density and gravel considered where relevant. An extracted amount is not automatically all crop-available, and the result is not itself a fertiliser rate.

Priority limitations / evidence

Interpreted requirements (kg/ha)

Sample zones / GPS locations / depths to check

Prescription / Nutrients supplied per hectare

Cost per hectare / staged priorities

Follow-up testing / decision to review

Put your soil results to work with Jimmy.

James White can discuss how existing reports or comprehensive soil testing could inform a Hybrid-Ag prescription for your paddock. You can also register interest in a soil-testing webinar; dates and presenters are to be confirmed.

Soil testing and interpretation

Hybrid-Ag combines comprehensive soil analysis with agronomic interpretation, calculating relevant Nutrient requirements in kg/ha to develop a practical prescription.

Know what the prescription needs to supply

Understand which deficits or excesses warrant action and what the blend and rate supply per hectare.

Comparison	Standard soil test	Hybrid-Ag soil test + interpretation
Analysis	Measures the soil properties and Nutrients included in the chosen panel. Scope and methods vary.	Major and Trace Elements with relevant soil properties, including pH, EC, organic Carbon and exchangeable cations. Confirm the panel.
Interpretation	Reports readings, units and any ratings. The advice and calculations included depend on the service.	Calculate Nutrient requirements in kg/ha towards soil balance, with sampling depth, soil-mass basis and laboratory method accounted for.
Next step	Provides a baseline of measured soil properties. Recommendations or a tailored application plan may be included.	Develop a Hybrid-Ag prescription for the requirements, crop demand, inputs, budget and equipment; check what the blend and rate supply.

Standard services may already include comprehensive panels and detailed advice. Compare the actual analysis, methods and interpretation provided.

Review progress across seasons

Comparable repeat tests can help review soil corrections. Keep sampling area, depth, timing and method consistent; review changes alongside crop performance and management records to plan next season's work.

The full soil requirement may need staging over several seasons; it is not automatically a one-season application rate.

Analyse	Interpret	Prescribe and review
Measure the sampled soil	Calculate requirements in kg/ha	Plan corrections and reassess

> Root conditions, water, weather and crop stage affect Nutrient access. Soil results alone do not prove crop uptake; plant testing or further investigation may be needed.
